***Abstract*—Community recognition continues to be a significant difficulty in the analysis of complex networks, especially in dynamic and stochastic contexts where communities change over time. Conventional spectral clustering and Markovian models either include structural regularities or temporal dependencies, although frequently lack the ability to amalgamate both within a cohesive theoretical framework. This study presents a Fourier operator framework inspired by quantum walks that integrates spectral graph theory, Markov processes, and quantum brain dynamics for the discovery of modular structures. We specifically build Fourier–Markov operators based on quantum walk principles to encapsulate both global frequency components and local transition dynamics of evolving networks. Our system utilizes superposition and interference effects by mapping random walks into a quantum-inspired Hilbert space, therefore uncovering latent modular structures with enhanced resolution. The resultant operator family facilitates interpretable community partitions, scalable computation using hybrid classical-quantum methodologies, and resilient detection across temporal snapshots. Experimental assessments on benchmark dynamic networks—encompassing social, biological, and financial graphs—indicate that our approach attains enhanced modularity optimization, temporal stability, and uncertainty calibration relative to leading community detection benchmarks. This study emphasizes the promise of quantum-spectral operators as a novel basis for examining Markovian community dynamics in intricate systems.**

***Index Terms*—Community Detection, Dynamic Networks, Markovian Dynamics, Graph Fourier Transform, Quantum Walks, Quantum-Inspired Neural Operators, Spectral Graph Theory, Modularity Optimization**

I. Introduction

Accurate community detection not only enhances our understanding of system organization but also underpins critical downstream tasks such as anomaly detection, recommendation, and resilience analysis [1], [2]. Despite substantial advancements, current methodologies continue to face challenges in simultaneously capturing the **spectral signatures** and **stochastic dynamics** that are intrinsic to the evolution of networks.

*Corresponding author: daozheng.qu@ieee.org

Yanfei Ma, Daozheng Qu, and Yibo Wang contributed equally and are co–first authors.

Traditional approaches can be broadly divided into two categories: **spectral approaches** and **probabilistic/dynamical approaches**. Spectral methods, such as eigen-decomposition of the graph Laplacian, employ Fourier-like transformations to uncover low-dimensional structures [3], [4]. However, these techniques are often sensitive to noise and frequently neglect temporal correlations. By contrast, **Markovian and random walk–based methods** utilize stochastic transition dynamics to infer modular partitions, effectively modeling temporal behaviors but often overlooking the fine-grained structural details encoded in the frequency domain [5]. These limitations motivate the search for a unified paradigm that integrates **spectral resolution, probabilistic modeling, and temporal evolution**.

Recent developments in **quantum information processing** offer promising inspiration for such a paradigm. **Quantum walks**, the quantum analogue of classical Markov processes, exhibit unique phenomena such as superposition and interference, enabling richer exploration of network topologies [6]. In addition, **quantum Fourier operators** have shown the ability to encode global and local structural patterns in a Hilbert space formalism [7]. These advances suggest that a **quantum-inspired operator framework**—capable of bridging **spectral graph theory, stochastic dynamics, and modular optimization**—can provide a more powerful and holistic approach for community detection in complex networks.

Qu and colleagues have previously demonstrated the efficacy of **Markov-guided Bayesian neural frameworks** in terms of long-horizon sequence forecasting and community tracking [8], as well as the potential of **deep learning architectures such as LSTM** in modeling environmental risk patterns in real-world networks [9]. These contributions emphasize the potential of integrating **probabilistic dynamics, temporal modeling, and community analysis**; however, they do not yet include the spectral and quantum-inspired operators that are required to capture more complex modular structures.

In this work, we introduce a **quantum walk–inspired Fourier operator framework** for detecting modular structures in dynamic networks governed by Markovian dynamics. Our

contributions are threefold:

- **Operator Design**: We construct a family of Fourier–Markov operators that integrate spectral decomposition with stochastic transition probabilities, grounded in the principles of discrete-time quantum walks.
- **Hybrid Embedding**: By mapping random walk processes into a quantum-inspired Hilbert space, our method captures both frequency-domain characteristics and probabilistic evolution, enabling interpretable and scalable modular partitions.
- **Empirical Validation**: We evaluate the proposed framework on synthetic and real-world dynamic networks, demonstrating superior performance in terms of modularity maximization, temporal stability, and robustness compared to state-of-the-art baselines.

II. Related Work

Various perspectives have been employed to investigate community detection, such as probabilistic models, spectral methods, and, more recently, quantum-inspired approaches. The most pertinent directions are examined in this section.

A. Spectral and Fourier-Based Methods

Spectral approaches were among the first to reveal modular networks. For cluster identification, the graph's eigendecomposition Laplacian provides a suitable embedding space. The Graph Fourier Transform (GFT) applies Fourier analysis to irregular domains, making graph signal processing tasks like denoising, filtering, and clustering easier. While these methods excel at capturing global connectedness, they may neglect temporal connections and be sensitive to noise [10], [11].

Random Walk and Markovian Methods Markov and random walks have long been utilized for community discovery. Walks and models inspired by quantum walks, which are quantum equivalents of conventional random walks, are powerful network analysis tools. They illustrate superposition and interference, enabling a deeper understanding of network architecture [12]. Recent study highlights their potential for community discovery, with applications in graph isomorphism and centrality analysis [7]. Recent research has explored hybrid optimization algorithms like QAOA and quantum-inspired neural networks (QNNs) for modularity optimization and clustering. Systematic integration of quantum walks, Fourier operators, and Markovian dynamics for community detection is underexplored despite recent [13], 2025.

B. Toward Unified Operator-Theoretic Frameworks

Quantum information theory has investigated Fourier-based operators in Hilbert spaces for structural analysis, while graph signal processing has begun to integrate probabilistic dynamics. Parallel to this, Qu and colleagues have illustrated the feasibility of integrating **Markov-guided Bayesian neural frameworks** for sequence forecasting and community tracking and LSTM-based models for real-world hazard detection. These studies underscore the potential of integrating deep learning and Markovian dynamics; however, they do not integrate spectral and quantum operators into community detection. This is the impetus behind our proposed **Quantum Walk–Inspired Fourier Operator Framework**, which integrates spectral decomposition, Markovian dynamics, and quantum walk principles to facilitate the detection of modular structure in dynamic networks.

III. Methodology

Our proposed framework integrates **quantum walk dynamics, Fourier spectral operators, and Markovian processes** into a unified operator-theoretic approach for community detection. The methodology consists of three stages: (1) Markovian modeling of dynamic graphs, (2) Quantum walk–inspired Fourier operator design, and (3) Community partition via modular optimization.

A. Markovian Modeling of Dynamic Graphs

We represent a dynamic network as $G_t = (V, E_t, W_t)$, where V is the set of nodes, E_t the temporal edges, and W_t the edge weights at time t.

A discrete-time Markov process is defined by the transition probability matrix:

$$P_t(i,j) = \frac{W_t(i,j)}{\sum_k W_t(i,k)}. \tag{1}$$

Here, $P_t(i,j)$ denotes the probability of transitioning from node i to node j. To account for temporal evolution, we aggregate over T snapshots:

$$\mathcal{M} = \frac{1}{T}\sum_{t=1}^{T} P_t, \tag{2}$$

yielding an operator that represents the average stochastic flow across time.

B. Quantum Walk–Inspired Fourier Operator Design

Unlike classical random walks, quantum walks evolve in a Hilbert space, where states are superpositions of node positions. Inspired by this principle, we lift $\mathcal{M}$ into a unitary operator:

$$U = e^{i\mathcal{L}}, \tag{3}$$

where $\mathcal{L}$ is the normalized graph Laplacian and $i = \sqrt{-1}$.

We then define the **Fourier–Markov operator**:

$$\mathcal{F}_Q = \Phi^\top U \Phi, \tag{4}$$

where Φ contains the eigenvectors of $\mathcal{L}$ as a graph Fourier basis. This operator encodes both spectral modes and quantum-inspired transition dynamics:

- Low-frequency modes $\rightarrow$ coherent community structures.
- High-frequency modes $\rightarrow$ community boundaries and anomalies.
- Superposition effects $\rightarrow$ overlapping community memberships.

C. Community Partition via Modularity Optimization

We extend the modularity function to the quantum–spectral setting:

$$Q(\mathcal{F}_Q, C) = \sum_{c \in C} \left(\sum_{i,j \in c} \mathcal{F}_Q(i,j) - \gamma \frac{k_i k_j}{2m} \right), \tag{5}$$

where C is the community partition, k_i is the degree of node i, m is the number of edges, and γ controls resolution.

Partitioning proceeds in two steps:

1) **Spectral Initialization:** Cluster embeddings from dominant eigenvectors of $\mathcal{F}_Q$ using k-means.
2) **Quantum Refinement:** Refine partitions via QAOA-inspired search or simulated annealing for high-modularity partitions.

D. Algorithmic Summary

Algorithm 1 QFM-CommNet Framework

Input: Dynamic network sequence $\{G_t\}_{t=1}^{T}$
Output: Community partition C

Construct transition matrices $\{P_t\}$ and compute $\mathcal{M} = \frac{1}{T}\sum_{t=1}^{T} P_t$ Compute Laplacian $\mathcal{L}$ and unitary operator $U = e^{i\mathcal{L}}$ Perform Graph Fourier Transform using eigenbasis Φ Construct Fourier–Markov operator $\mathcal{F}_Q = \Phi^\top U \Phi$ Extract embeddings from dominant eigenvectors of $\mathcal{F}_Q$ Apply spectral clustering to obtain initial partition C Refine C using modularity-based quantum optimization **return** C

1) Computational Considerations:

- **Scalability:** Spectral decomposition is approximated via Lanczos iteration, ensuring tractability for large graphs.
- **Quantum Compatibility:** The unitary operator U can be implemented on quantum simulators, supporting hybrid computation.
- **Interpretability:** $\mathcal{F}_Q$ provides a spectral lens for analyzing modular dynamics, balancing mathematical rigor with physical intuition.

IV. Evaluation

We conduct extensive experiments on both synthetic and real-world dynamic networks to validate the efficacy of the proposed Quantum Walk–Inspired Fourier Operator Framework (QFM-CommNet). Our assessment emphasizes three critical components: (1) **community quality**, (2) **temporal stability**, and (3) **computational efficiency**.

A. Datasets

We evaluate QFM-CommNet on four categories of datasets to ensure diversity and reproducibility:

- **Synthetic (LFR, SBM):** Graphs with 5,000–10,000 nodes and 20,000–50,000 edges, simulated over 20 temporal snapshots; undirected and unweighted; preprocessing removes isolated nodes and normalizes community size distribution.
- **Social (Enron, DBLP):** Networks with 10,000–50,000 nodes and up to 200,000 edges per snapshot, aggregated into 50–200 monthly snapshots; directed and unweighted; preprocessing includes timestamp alignment and removal of duplicate interactions.
- **Biological (PPI, Brain fMRI):** Networks ranging from 2,000–20,000 nodes with weighted undirected edges, observed over 30–100 time steps; edge weights are normalized, and low-confidence interactions are pruned by applying a threshold of 0.05.
- **Financial (Stock, Crypto):** Dense weighted correlation networks with 500–2,000 nodes and complete connectivity per snapshot, covering ~ 500 daily snapshots; edges are computed via rolling-window Pearson correlation and Fisher-z transformation, followed by sparsification at the 0.1 quantile.

TABLE I
Performance comparison of QFM-CommNet against baseline methods on dynamic networks

Method	Modularity (Q)	NMI	ARI
Spectral Clustering	0.412 ± 0.015	0.621 ± 0.012	0.534 ± 0.018
MCL	0.458 ± 0.017	0.654 ± 0.010	0.562 ± 0.016
Infomap	0.472 ± 0.016	0.671 ± 0.011	0.589 ± 0.015
Quantum Walk	0.495 ± 0.014	0.683 ± 0.009	0.601 ± 0.012
GNN + Modularity Loss	0.518 ± 0.013	0.701 ± 0.010	0.624 ± 0.014
QFM-CommNet (Ours)	**0.561 ± 0.010**†	**0.739 ± 0.009**†	**0.671 ± 0.011**†

Results are reported as mean ± std over 5 random seeds. Best results are in **bold**. † indicates significant improvement over the second-best ($> 1\sigma$).

B. Baselines

We conduct a comparison of QFM-CommNet with a number of cutting-edge community detection methods:

- **Spectral Methods:** Laplacian eigenmaps, the normalized cut, and graph wavelet clustering are all examples of Markovian methods. Markov Clustering (MCL) and information mapping.
- **Quantum-Inspired Methods:** Quantum walk–based modularity maximization and QAOA-based graph partitioning.
- **The following is a list of deep learning approaches:** Modularity loss and Bayesian community tracking models were employed to train graph neural networks (GNNs).

C. Evaluation Metrics

We utilize metrics that are commonly used to identify communities:

- **Modularity** (Q): Quantifies the level of community structure in comparison to a null model.

QFM-CommNet (Ours)	**13.9**	**122.7**	**641.5**	**1412.8**

- **Normalized Mutual Information (NMI)**: Quantifies the alignment between the detected and ground-truth communities.
- **Adjusted Rand Index (ARI)**: Assesses the consistency of clustering while accounting for chance.
- **Temporal Smoothness (TS)**: Defines the stability of partitions over a series of snapshots. Runtime and Scalability: Analysis of wall-clock time and complexity in networks of increasing magnitude.

D. Experimental Setup

The investigations are conducted on a workstation equipped with a 256 GB RAM and an NVIDIA A100 GPU, and are implemented in Python using network analysis libraries (NetworkX, PyTorch Geometric). For hybrid quantum optimization, we utilize Qiskit simulators with 20 qubits and implement QAOA with a depth of $p \leq 3$. Cross-validation is implemented to optimize hyperparameters.

TABLE III
ABLATION STUDY ON QFM-COMMNET COMPONENTS. REMOVING FOURIER OR QUANTUM MODULES REDUCES PERFORMANCE.

Model Variant	Modularity (Q)	NMI	ARI
Without Fourier Operator	0.492	0.681	0.597
Without Quantum Walk	0.503	0.694	0.609
Without Markov Aggregation	0.511	0.702	0.617

V. RESULTS AND CONCLUSION

A. Results

Tables I and II show the benefits of the proposed QFM-CommNet system. QFM-CommNet consistently surpasses baseline techniques in all evaluation parameters for community quality. It has the maximum modularity ($Q = 0.561$), normalized mutual information (NMI = 0.739), adjusted Rand index (ARI = 0.671), and temporal smoothness (TS = 0.593). These findings show that Fourier spectral operators, Markovian transition dynamics, and quantum walk principles better characterize community structures.

The computational efficiency of QFM-CommNet is comparable to that of classical spectral and random walk-based approaches. According to Table II, its runtime scales polynomially with network size and remains competitive even on 100K node networks. Tables III results show that the Lanczos-based spectral approximation is efficient and suited for large and dynamic graphs.

B. Conclusion

This study presents **QFM-CommNet**, an innovative operator-theoretic framework for community detection in dynamic networks, influenced by quantum walks and graph Fourier analysis. By integrating Markovian dynamics into a quantum-inspired spectrum operator, the framework attains elevated detection accuracy and interpretability. The suggested method exceeds leading benchmarks on modularity optimization, temporal stability, and computing efficiency.The approach extends beyond community discovery, facilitating larger applications in dynamic graph mining, such as anomaly detection, influence analysis inside social networks, and risk propagation in financial systems. Future research will examine hybrid implementations on quantum hardware and develop extensions to multimodal and heterogeneous dynamic networks.
